

Tables of linear cellular automata for minimal weight primitive polynomials of degrees up to 300

K. Cattell and J. Muzio
Department of Computer Science
University of Victoria

Abstract

This technical report contains a table of linear cellular automata for certain primitive polynomials. For each degree from two to 300, the table lists a primitive polynomial of minimal weight (least possible number of non-zero coefficients), and its corresponding cellular automaton. The polynomials are from the tables compiled by Bardell, McAnney and Savir, which can be found in [1]. The table is computed using the recent algorithm due to Cattell and Muzio [2]. The time required to find each cellular automaton is also included.

1. Introduction

Cellular automata (CAs) have recently been explored for pattern generation and data compaction (signature analysis). Some have been found to have very good randomness properties, based on standard randomness tests, providing better pseudo-random patterns than linear feedback shift registers (LFSRs). CAs often have lower probability of aliasing than LFSRs when used as data compactors [3,6]. Also, the possible use of CAs for delay fault testing is explored in [3,6]. See [4] for an introduction to CAs.

CAs are linear finite state machines, and so they have *characteristic* polynomials from which some of their properties can be determined. Given a CA, it is very easy to calculate its characteristic polynomial (n shift-and-add operations)[4]. There have been two major open questions about the characteristic polynomials of CAs. Firstly, given a polynomial, can we efficiently calculate its corresponding CA, if it exists? Secondly, do all irreducible polynomials have corresponding CAs? The first question has been answered by Cattell and Muzio in [2], where a fast algorithm for determining the CA for a given polynomial is presented.

2. The table

The table has three columns: a polynomial, the time required by the program to find its corresponding CA, and its CA. The following is a more detailed description of each column.

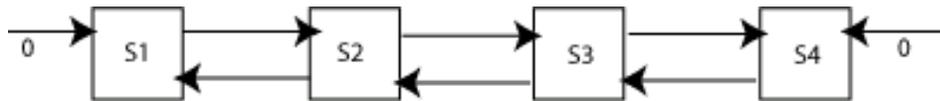

The tables list one polynomial for each degree from two to 300. The *weight* of a polynomial is the number of non-zero coefficients. Each polynomial is *lowest-weight* primitive, meaning that there is no primitive polynomial of that degree with a lower weight. The polynomials are from [1], and are represented by listing their non-zero coefficients. For example, the entry 31 3 0 represents the polynomial $x^{31} + x^3 + 1$.

The second column lists the time that the program required to find the CA for the polynomial, measured in seconds. The program is written in C++, and was run on a Sun 3/280.

The third column lists the main diagonal of the CA corresponding to the polynomial. For example, the entry 0101 represents the CA

$$\begin{bmatrix} 0 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix}$$

This machine is shown in the following picture:

where the next state computations for the cells are:

$$\begin{aligned} s_1^+ &= 0 + s_2 \\ s_2^+ &= s_1 + s_2 + s_3 \\ s_3^+ &= s_2 + s_4 \\ s_4^+ &= s_3 + s_4 + 0 \end{aligned}$$

See [4] for more information on the next state computation of a CA.
